**New whooping cough vaccine suspected of triggering rise in eczema and
asthma cases About the author: Bryan Hubbard
<[hp://www.wddty.com/people/bryan-hubbard](http://www.wddty.com/people/bryan-hubbard)>**

**Around a quarter of small children suffer from an atopic disease, such as
eczema, asthma or a food allergy – and a group of researchers suspects the
pertussis (whooping cough) element of the DTP vaccination could be to
blame. The severity of the disease has worsened in the past 20 years or
so – some cases have needed hospital care – and is a trend that coincides
with the introduction of a new version of the vaccine, from whole-cell
pertussis to acellular pertussis. In Australia – where the research team is
based – the switch started in 1997, and there was almost immediately a
'second wave' of atopic cases, after the problem had peaked in the 1980s
and had started to decline. The researchers, from the Wesfarmers Centre
of Vaccines & Infectious Diseases in Perth, say that one allergy clinic
reported a 12-fold increase in cases, and incidence of fatal anaphylactic
shock to food rose by 10 per cent. Around 18 per cent of infants developed
a food sensitivity, and 26 per cent suffered from allergic eczema
<[hps://www.wddty.com/magazine/2014/july/eczema.html](https://www.wddty.com/magazine/2014/july/eczema.html)> . Similar
increases were being reported in the US and UK around the time when
the new acellular vaccine was also being introduced. The researchers will
be working with clinics across Australia to compare the health of infants
born between 1997 and 1999 who either had the whole-cell or acellular
vaccines. They will be compared to a group of 500 children who have a
food allergy.**
